Abstract

To improve individual health evaluation, blood plasma samples of essentially healthy male and female citizens of Blagoveschensk (18 to 35 y/o) were analyzed under the scanning electron microscope. In 84.84% of samples, compound morphogenesis of elementary bodies, their conglomerates and daughter individuals matched the L-form bacteria. Dynamics of morphotypes detected in plasma mirrored the immunobiological state of organism, which can benefit to individual health monitoring.
